PATENT 450100-03598

IN THE CLAIMS

This listing of claims will replace all prior versions, and listings, of claims in the application. An identifier indicating the status of each claim is provided.

Listing of Claims:

 (Currently Amended) A signal processor for processing a predetermined unit of input data containing a variable length code and information providing the active length of the variable length code, said signal processor comprising:

input means for inputting the input data;

start detecting means for detecting a start of the predetermined unit of the input data, in which the predetermined unit corresponds to a frame;

means for receiving a frame end signal that is synchronized with end of frame data and is indicative of the end of each of a number of frames;

end detecting means for detecting the end of a respective frame based on the frame end signal; and

signal processing means for processing executing an action on the variable length code active at the start detected by said start detecting means, for making the action on the variable length code inactive at the end detected by said end detecting means, and for initializing the state of the action on the variable length code at the end detected by said end detecting means,

wherein the level of an enable signal is generated altered between a high level and a low level based on a frame end signal and a result of a detected start code,

wherein, when the start of a frame is not detected, the data received after the frame end signal of the previous frame and before the start of a next frame is not processed and is designated invalid allowing immediate processing of the next frame thereby eliminating invalid data and reducing further lost data.

- (Original) A signal processor according to Claim 1, wherein the input data comprises MPEG encoded data.
- (Original) A signal processor according to Claim 1, further comprising recording means for recording the output of said signal processing means.
- 4. (Currently Amended) A signal processing method for processing a predetermined unit of input data containing a variable length code and information providing the active length of the variable length code, said signal processing method comprising the steps of:

inputting the input data;

detecting a start of the predetermined unit of the input data input in said inputting step, in which the predetermined unit corresponds to a frame;

receiving a frame end signal that is synchronized with end of frame data and is indicative of the end of each of a number of frames;

detecting the end of a respective frame based on the frame end signal; and

PATENT 450100-03598

U.S. Appln. No. 10/002,661 Reply to Office Action dated November 15, 2007

performing processes to process-execute an action on the variable length code

active at the start detected in said start detecting step, to make the action on the variable length

code inactive at the end detected in said end detecting step, and to initialize the state of the action

on the variable length code at the end detected in said end detecting step,

wherein the level of an enable signal is generated altered between a high level and

a low level based on a frame end signal and a result of a detected start code,

wherein, when the start of a frame is not detected, the data received after the

frame end signal of the previous frame and before the start of a next frame is not processed and

is designated invalid allowing immediate processing of the next Frame thereby eliminating

invalid data and reducing further lost data.

5. (Original) A signal processing method according to Claim 4, further

comprising the step of recording the result of said process performing step.

6. (Previously Presented) The signal processor according to claim 1,

wherein the means for receiving includes a flip-flop circuit.

7 (Currently Amended) A method for processing frames of data

comprising:

Frommer Lawrence & Haug LLP 745 Fifth Avenue New York, NY 10151

PATENT 450100-03598

Reply to Office Action dated November 15, 2007

synchronizing a frame end signal with end of frame data that indicates an end of each of a number of frames;

processing each frame until the end of frame data is detected;

suspending skipping processing data [[for]] of a period of time, the period of time being from the end of frame data to a subsequent start signal, when an error is detected;

detecting a start code for a corrected stream of data:

re-initiating the processing step as a function of the detecting step; and

designating data received after the frame end signal and before the start of a next frame invalid.

wherein the level of an enable signal is generated altered between a high level and a low level based on a frame end signal and a result of a detected start code,

wherein, when the start of a frame is not detected, the data received after the frame end signal of the previous frame and before the start of a next frame is not processed and is designated invalid allowing immediate processing of the next frame thereby eliminating invalid data and reducing further lost data.
